

Overview

The data and code in this replication package reproduce all tables and figures in Hengel (2022). Raw data are in the `0-data/fixed` directory. Transformed data, estimation results and figures are saved in the `0-data/generated`, `0-tex/generated` and `0-images/generated` directories, respectively. The replication code, described in detail below, will take about 11 hours to run.

The data in this replication package are publicly available and licensed under a Creative Commons Attribution 4.0 International License. See [LICENSE.txt](#) for details.

Data

Main dataset: `read.db`

Almost all figures and tables in Hengel (2022) were generated using the raw data in `0-data/fixed/read.db`. `read.db` is an SQLite database of biblio- and biographic data on articles and authors published in the *American Economic Review* (*AER*), *Econometrica*, *Journal of Political Economy* (*JPE*), *Quarterly Journal of Economics* (*QJE*) and the *Review of Economic Studies* (*REStud*). `read.db` contains 12 tables. Their contents and provenance are described below. Figure 1 displays `read.db`'s entity-relationship diagram; Table 1 describes each column. Please see Hengel (2022), Section 2 and Appendices C and D (online appendix) for additional details on data provenance and variable construction.

- **Article.** The Article table contains bibliographic information from every English-language article published with an abstract in the *AER*, *Econometrica*, *JPE* and *QJE* between January 1950 and December 2015 (inclusive). It also contains data on *REStud* articles published with submission and acceptance dates during that same period.

All data were collected from publicly available sources (*e.g.*, publishers' websites and JSTOR). The exception is citations which were obtained from [Web of Science](#) in September 2017 and January 2018. (*Citation data are proprietary to Web of Science and are included here for replication purposes only; please do not distribute these data or publish online.*) Data on submit-accept times and institutions were collected from journals' online archives, extracted from digitised articles using the open source command utility `pdftotext` or entered manually by me or a research assistant.

The column **Abstract** contains unicode textual data of articles' abstracts. When using the data, please ensure it is imported with the proper encoding (*e.g.*, `encoding("utf-8")` in Stata (14+) or `iconv(, from="macintosh", to="UTF-8")` in R).

- **Author.** The Author table contains biographic details on authors. Gender was initially assigned using [GenderChecker.com](#)'s database of male and female names. Three separate Mechanical Turk workers, a research assistant or I then manually verified them based on photos and other information found on faculty websites, Wikipedia articles, *etc.* In situations where the author could not be found, I emailed or telephoned colleagues and associated institutions.

Authors were assumed to be native-English speakers if one or more of the following criteria were satisfied: (i) they were raised in an English-speaking country; (ii) they obtained all post-secondary education from English speaking institutions; or (iii) they spoke with no discernible non-native accent. This information was almost always found on authors' CVs, websites, Wikipedia articles, faculty bios or obituaries. In a small number of cases the criteria were ambiguously satisfied or not available; in these instances I asked friends and colleagues of the author or inferred English fluency from the author's first name, country of residence or surname (in that order). If one co-author on a paper was found to be a native English speaker, I did not necessarily check whether any of the other co-authors were also native English speakers.

- **AuthorCorr.** The AuthorCorr table maps **AuthorID** in Author to **ArticleID** in Article.
- **Children.** The Children table contains data on the year female authors with at least one exclusively female-authored paper published in *Econometrica* gave birth. This information was obtained from authors' published profiles, CVs, acknowledgements, Wikipedia, personal websites, Facebook pages, background checks and by consulting local school district/popular extra-curricular activity websites. Exact years were recorded whenever found; otherwise, they were approximated by subtracting a

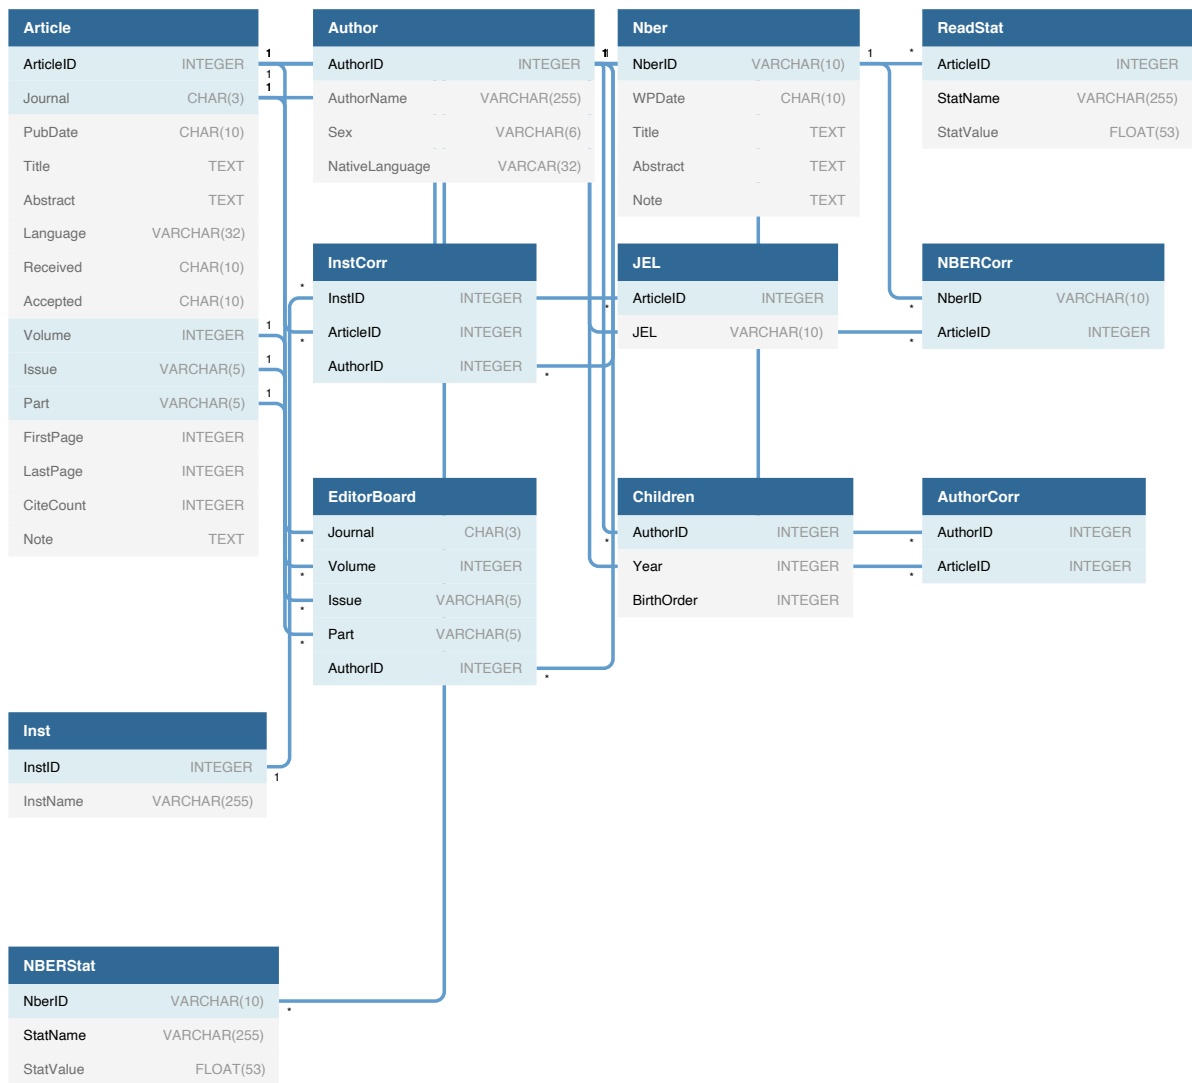

Figure 1: Entity-relationship diagram for `read.db`

child’s actual or estimated age from the date the source material was posted online. In several instances, I obtained or verified this information from acquaintances, friends and colleagues or by asking the woman directly. If an exhaustive search turned up no reference to children, I assumed the woman in question did not have any.

Please note that data on children’s birth years were only systematically collected for children potentially born during the time a woman had an exclusively female-authored paper under review at *Econometrica*.

- **EditorBoard.** The EditorBoard table contains the **AuthorID** for every editor and each issue of a journal. Editors were identified from issue mastheads.
- **Inst.** The Inst table maps each unique **InstID** to an institution name.
- **InstCorr.** The InstCorr table maps each (**ArticleID**, **AuthorID**) combination in AuthorCorr to at least one **InstID** in Inst.
- **JEL.** The JEL table maps *JEL* codes to each **ArticleID** in Article. The *JEL* system was significantly revised in the 1990s; because exact mapping from one system to another is not possible, I collected these data only for articles published post-reform. Codes were recorded whenever found in the text of an article or on the websites where bibliographic information was scraped. Remaining articles were classified using data from the American Economic Association’s Econlit database.
- **NBER.** The NBER table contains basic bibliographic data on the NBER working papers that were eventually published in a top-four journal. Data were scraped from the [NBER website](#) or extracted from digitised working papers.
- **NBERCorr.** The NBERCorr table maps each **NberID** in NBER to at least one **ArticleID** in Article. (The mapping is not one-for-one because a small number of working papers were eventually published as multiple articles or combined into one.) Matches were identified using citation data from [RePEc](#) and by searching NBER’s database directly for unmatched papers authored by NBER family members. The column **Note** contains notes in situations where the matching process involved some degree of ambiguity (*e.g.*, because of title changes between draft and final versions of the paper).
- **ReadStat.** The ReadStat table contains readability statistics for every article with an abstract in Article. Readability scores were generated with the Python module **Textatistic** using the text in the **Abstract** column of the Article table. **Textatistic**’s code and documentation are available on [GitHub](#); a brief description is provided in Hengel (2022), Appendix D.3.
- **NberStat.** The NberStat table contains readability statistics calculated from the **Abstract** text of every working paper in the NBER table. Statistics were generated using the Python module **Textatistic**.

Table 1: Description of variables in `read.db`

Table	Column name	Description
Article	ArticleID	Unique ID for each article
Article	Journal	Journal (<i>AER</i> , <i>ECA</i> , <i>JPE</i> , <i>QJE</i> , <i>RES</i> , <i>P&P</i>)
Article	PubDate	Date of publication (YYYY-MM-DD)
Article	Title	Title
Article	Abstract	Abstract
Article	Language	Language (<i>e.g.</i> , English or French)
Article	Received	Date (YYYY-MM-01) manuscript first submitted
Article	Accepted	Date (YYYY-MM-01) manuscript finally accepted
Article	Volume	Volume
Article	Issue	Issue
Article	Part	Part
Article	FirstPage	First page number
Article	LastPage	Last page number
Article	CiteCount	Citation count (Web of Science)
Article	Note	Notes on observation

Table	Column name	Description
Author	AuthorID	Unique ID for each author
Author	AuthorName	Author name
Author	Sex	Author gender
Author	NativeLanguage	Native-English speaking indicator (English, Non-English, Unknown)
AuthorCorr	AuthorID	Unique ID for each author (maps to Author table)
AuthorCorr	ArticleID	Unique ID for each article (maps to Article table)
Children	AuthorID	Unique ID for each author (maps to Author table)
Children	Year	Year a child was born
Children	BirthOrder	Order of birth if two children are born in the same year
EditorBoard	AuthorID	Unique ID for each editor (maps to Author table)
EditorBoard	Journal	Journal
EditorBoard	Part	Part
EditorBoard	Volume	Volume
EditorBoard	Issue	Issue
Inst	InstID	Unique ID for each institution
Inst	InstName	Institution name
InstCorr	InstID	Unique ID for each institution (maps to Inst table)
InstCorr	ArticleID	Unique ID for each article (maps to Article table)
InstCorr	AuthorID	Unique ID for each author (maps to Author table)
JEL	ArticleID	Unique ID for each article (maps to Article table)
JEL	JEL	Tertiary <i>JEL</i> code
NBER	NberID	Unique ID for each NBER working paper
NBER	WPDate	Date (YYYY-MM-DD) manuscript was released as a working paper
NBER	Title	Working paper title
NBER	Abstract	Working paper abstract
NBER	Note	Notes on observation and/or matching process
NBERCorr	NberID	Unique ID for each NBER working paper (maps to NBER table)
NBERCorr	ArticleID	Unique ID for each article (maps to Article table)
ReadStat	ArticleID	Unique ID for each article (maps to Article table)
ReadStat	StatName	Name of statistic (<i>e.g.</i> , flesch)
ReadStat	StatValue	Value of statistic
NBERStat	NberID	Unique ID for each NBER working paper (maps to NBER table)
NBERStat	StatName	Name of statistic
NBERStat	StatValue	Value of statistic

Other datasets

A small number of figures and tables in Hengel (2022) are generated from data contained in `introduction_text.txt`, `readability_corr.txt` and `JEL.csv`. Their contents and provenance are described below and in Table 2.

- **introduction_text.txt.** This file contains the first paragraph of text to come after a heading explicitly titled “Introduction” in NBER working papers eventually published in top-four journals. Data are used to generate Figure D.2 in Appendix D.2 in Hengel (2022). Textual data kindly provided by Henrik Kleven and Dana Scott.
- **readability_corr.txt.** This file contains coefficients of correlations between the five readability scores used in Hengel (2022) and alternative measures of text difficulty. These figures are from the studies listed in Appendix D.4. They are used to produce the top graphic of Figure D.1 in Appendix D.1.
- **JEL.csv.** The file `JEL.csv` categorises all tertiary *JEL* codes as either theory/methodology, empirical or other. Categorisation was done manually by me. Data in `JEL.csv` are used to generate Table C.1 and construct the theory/methodology, empirical and other dummies described in Appendix C.

Table 2: Description of variables in other datasets

File name	Column name	Description
introduction_text.txt	NberID	Unique ID for each NBER working paper
introduction_text.txt	Text	First paragraph of text
readability_corr.txt	StatName	Name of readability statistic
readability_corr.txt	Correlation	Coefficient of correlation
readability_corr.txt	Test	Name of alternative measure of text difficulty
readability_corr.txt	TestType	Type of alternative measure
readability_corr.txt	Source	BibTeX label for source study (<i>e.g.</i> , SurnameYYYY)
readability_corr.txt	Note	Notes on calculations, <i>etc.</i>
JEL.csv	JEL	Tertiary <i>JEL</i> code
JEL.csv	Description	Long name of <i>JEL</i> code
JEL.csv	Type	Classification (empirical, theory or other)

Code

Software requirements

- Python 3.9.0
 - Textatistic 0.0.1
 - Please see below for instructions on how to install this package.
- R 4.1.2
 - RSQLite (2.2.9)
 - tidyverse (1.3.1)
 - haven (2.4.3)
 - remotes (2.4.2)
 - lexicon (1.3.1, from <https://github.com/trinker/readability>)
 - textclean (0.9.7, from <https://github.com/trinker/readability>)
 - textshape (1.7.4, from <https://github.com/trinker/readability>)
 - syllable (0.2.0, from <https://github.com/trinker/readability>)
 - readability (0.1.2, from <https://github.com/trinker/readability>)
 - The file 2-update-readability.R installs the latest version of all dependencies.
- Stata 17.0
 - ftools (2.37.0)
 - estout (3.24)
 - psmatch2 (4.0.12)
 - xtabond2 (3.7.0)
 - listtex (25 September 2009)
 - reghdfe (5.7.3)
 - binscatter (7.02)
 - distinct (1.2.1)
 - labutil (1.0.0)
 - coefplot (1.8.5)
 - wordwrap (0.2, from <https://mloeffler.github.io/stata/wordwrap>)
 - The file 3-master.do locally installs the latest version of all dependencies.
- Mathematica 12.3.1

Optional portions of the code use bash scripting and WolframScript; instructions for installing the latter are provided below.

Instructions to replicators

To generate all figures and tables in Hengel (2022), first navigate to the project’s root directory and then copy 4-confidential-data-not-for-publication/read.db to data/fixed/read.db.¹ Next, execute

¹CiteCount is proprietary to Web of Science and are included here for replication purposes only; please do not distribute these data or publish online.

the following four steps.

1. Run `1-update-textatistic.py` in Python.
2. Run `2-update-readability.R` in R.
3. Run `3-master.do` in Stata.
4. Execute `Figure-3.nb` and `Figure-G.2.nb` (both in the `0-code/output` directory) in Mathematica.

Each step can be executed individually by following the steps outlined below. Alternatively, the Bash script `4-master.sh` completes all four steps automatically. To run `4-master.sh`, install the latest version of [WolframScript](#) and follow the instructions under the `1-update-textatistic.py` and `3-master.do` headings for installing `Textatistic` and an SQLite driver, respectively. Then, navigate to the project's root directory and issue the following command in a Bash shell:

```
sh 4-master.sh
```

`4-master.sh` was last run on 17 January 2022 on a 4-core Intel-based iMac running MacOS version 11.6.3. Computation took 14 hours, 58 minutes and 28 seconds.

1-update-textatistic.py

The Python script `1-update-textatistic.py` calculates readability scores for every article and NBER working paper with an abstract in `read.db` and updates its `ReadStat` and `NBERStat` tables with the results. More details on the `Textatistic` program are available on [GitHub](#). Documentation on how it calculates readability scores are available at [erinhengel.com](#).

For `1-update-textatistic.py` to work, you must first install the Python package `Textatistic`. If you're lucky, this can be done in a single step by issuing the following command in your terminal application:

```
pip install textatistic
```

But you're probably not lucky. The problem is the `PyHyphen` dependency; for reasons I do not fully understand, `pip` does not always properly install it before trying to install `Textatistic`.

If you encounter this error, you will need to install both `PyHyphen` and `Textatistic` from source. But don't panic; it's not that hard. Just navigate to the project's root directory and issue the following sequence of commands in your terminal application.²

```
cd "0-code/programs/Textatistic/required_packages/PyHyphen-2.0.5/"
sudo python setup.py install
cd ../../
sudo python setup.py install
```

Once `Textatistic` has been properly installed, navigate back to the project's root directory and run the following command in the terminal application.

```
python 1-update-textatistic.py
```

You will be alerted when the `ReadStat` and `NBERStat` tables in `read.db` have been successfully updated with the newly calculated readability statistics.

`1-update-textatistic.py` was last run on 16 January 2022 on a 4-core Intel-based iMac running MacOS version 11.6.3. Computation took 2 minutes and 7 seconds.

2-update-readability.R

The R script `2-update-readability.R` (R version 4.1.2) calculates readability scores using the R [readability package](#). To run it, open R, set the current working directory as the project directory and issue the following command:

```
source("2-update-readability.R")
```

`2-update-readability.R` first installs the latest version of `RSQLite`, `tidyverse`, `haven` and `remotes` from CRAN. It then installs `readability`, `syllable`, `textshape`, `textclean` and `lexicon` from [GitHub](#).

²`PyHyphen` may need to be installed using Python 3.7 or earlier.

Once these packages are installed and loaded, it connects to the `read.db` SQLite database, fetches published article and NBER abstracts, calculates readability scores and exports the results to `readstat.dta` and `nberstat.dta` in the `0-data/generated` directory. Finally, it reads in `introduction_text.txt`, calculates readability scores and exports the result to `articlestat.dta`, also in the `0-data/generated` directory.

`2-update-readability.R` was last run on 7 February 2022 on a 4-core Intel-based iMac running MacOS version 11.6.4 Computation took 2 minutes and 14 seconds to run.

3-master.do

The Stata script `master.do` (Stata version 17.0) generates all figures and tables in Hengel (2022) with the exception of Figure 3 and Figure G.2 (see below).

To run `master.do`, first install an SQLite driver—I use a driver from [Actual Technologies](#)—and update the file path in line 35 accordingly. Then, open a Stata terminal, navigate to the project’s root directory and issue the following command:

```
do 3-master.do
```

`3-master.do` first installs several third-party packages from SSC (`ftools`, `estout`, `psmatch2`, `xtabond2`, `listtex`, `reghdfe`, `binscatter`, `distinct`, `labutil` and `coefplot`) and `wordwrap` from [GitHub](#). It then copies the `ado`, `scheme`, `colors` and `estout` definition files in the `0-code/programs/stata` directory into your Stata personal `ado` directory. (Alternatively, manually load these files into Stata before running `3-master.do` and comment out lines 26–29.) It then transforms the raw data (results are saved in `0-data/generated`) and executes the Stata `do` files in the `0-code/output` directory. Estimation results are either saved as LaTeX output in the `0-tex/generated` directory or as image files in the `0-images/generated` directory. A log of all output is saved in the `0-log` directory as `YYYY-MM-DD-HH-MM-SS.smcl`.

`3-master.do` was last run on 10 February 2022 on a 4-core Intel-based iMac running MacOS version 11.6.4 Computation took 11 hours 7 minutes and 0 seconds.

Create Mathematica graphs

Figures 3 and G.2 in Hengel (2022) were created using Mathematica (version 12.3.1). To generate them, follow the three steps below:

1. Navigate to the `0-code/output` directory and open the files `Figure-3.nb` and `Figure-G.2.nb` in Mathematica.
2. Select “Evaluate Notebook” from the Evaluation dropdown menu.
3. Click “Yes” to run the initialisation cells.

`Figure-3.nb` generates `Figure-3.png`; `Figure-G.2.nb` generates `Figure-G.2.png`. Both files are saved in the `0-images/generated` directory.

`Figure-3.nb` and `Figure-G.2.nb` were last run on 16 January 2022 on a 4-core Intel-based iMac running MacOS version 11.6.3. Combined computation took less than a minute.
